

Connecting keja.app

Keja AI now runs on Vercel. The domain is already attached on the Vercel side — this guide covers the single remaining step: pointing the two DNS records at Spaceship at Vercel's edge network, then verifying that everything resolves correctly worldwide.

PRODUCTION URL

keja-ai-rho.vercel.app

CANONICAL URL

https://keja.app

PLATFORM

Vercel Edge

Overview — What This Guide Does

The Keja AI application is built as a static export from the Next.js 16 codebase and served from Vercel's global edge network. On 10 September 2026 production moved from Netlify to Vercel, and the site is live today at `keja-ai-rho.vercel.app`. This guide walks through the final step of that migration: making the custom domain `keja.app` (and `www.keja.app`) serve the exact same deployment at a clean, branded web address.

Because the Vercel side is already fully configured — the project exists, the production deployment is live, and both hostnames are attached to it — the only remaining work is a **two-record DNS change** at Spaceship, the registrar where `keja.app` is registered. DNS is the internet's address book: it translates `keja.app` into server addresses. Right now those addresses still point at the retired Netlify setup; they need to point at Vercel's anycast edge instead. Nothing in this guide touches the application code — the build pipeline already treats `https://keja.app` as the canonical URL, so no code changes are needed at any point.

How a visitor reaches the site after configuration:

1 · Browser

User types `keja.app`

2 · DNS lookup

Spaceship resolves the name to Vercel's edge (76.76.21.21)

3 · Vercel edge

CDN matches `keja.app` to the `keja-ai` project

4 · Keja AI

App served over HTTPS with auto-SSL

WHY THE MOVE FROM NETLIFY

Two Netlify-side blockers made the old setup impossible to finish: the `keja.app` apex was claimed by a second Netlify login (a dormant account conflict), and the account was hit by a platform bug that paused production deploys. Vercel needs neither a claim release nor a support ticket — the domain simply points at Vercel's edge via the two DNS records in this guide. The Netlify `keja-ai` site has been deleted as part of the migration.

Before You Start

Completing this checklist first avoids the most common causes of stalled domain setups. Each item takes a couple of minutes to verify, and every one of them has stopped a real deployment at some point, so it is worth being honest about each before touching any DNS settings.

- ☐ **The Vercel deployment is live.** Open `https://keja-ai-rho.vercel.app` in a browser and confirm the Keja AI app loads. This is the project's public production URL; the deploy pipeline (GitHub Actions → Vercel CLI prebuilt deploys) ships every push to `main` automatically. If it does not load, fix the deployment first — domain linking cannot help an unpublished site.
- ☐ **You can sign in to Spaceship** (`spaceship.com`) as the owner of `keja.app`, with permission to edit the domain's DNS records. The domain's nameservers are `launch1.spaceship.net` and `launch2.spaceship.net` — DNS is managed in the Spaceship dashboard, and those nameservers stay exactly as they are.
- ☐ **You can sign in to Vercel** (`vercel.com`, team *Victor's projects*) to watch the domain status turn green. Viewing is enough — no Vercel-side changes are needed; both domains are already attached to the `keja-ai` project.
- ☐ **You know whether `keja.app` currently has live email** (MX records for Google Workspace, Zoho, etc.). This guide only changes the `A` and `www CNAME` records, so email is untouched — but check anyway, so nothing on the account surprises you.
- ☐ **You have up to a few hours of patience.** DNS changes usually propagate in minutes, but TTL caching can extend the wait. The `.app` top-level domain is HTTPS-only (HSTS preloaded), so during propagation browsers will refuse plain HTTP — that is expected behaviour, not a misconfiguration.

SECTION 03

What Is Already Configured on Vercel

Everything on the Vercel side was set up during the migration and verified with live smoke tests. The table below is the current state — if you ever need to re-check it, the Vercel dashboard shows all of it under the `keja-ai` project:

Setting	State
Project	keja-ai — static export, deployed from GitHub Actions on every push to main
Production deployment	Live and promoted — serving at <code>keja-ai-rho.vercel.app</code>
keja.app	Attached as the primary custom domain — status "Pending" until DNS points at Vercel
www.keja.app	Attached as a redirect domain: 308 → <code>https://keja.app</code>
HTTPS	Automatic Let's Encrypt certificates, provisioned the moment DNS resolves — nothing to request or renew by hand
Routing & headers	SPA rewrite, service-worker no-cache and security headers compiled from <code>vercel.json</code>

The "Pending" status on `keja.app` is expected and healthy: Vercel verifies domain ownership by observing where DNS actually points. Until the records in the next section are changed, verification cannot succeed — and the moment they resolve to Vercel, the domain activates with no further clicks.

SECTION 04

Step 1 — Update the Two DNS Records at Spaceship

This is the only part of the process that happens outside Vercel, in the Spaceship dashboard. Exactly two records change: the apex `A` record that currently points at the retired Netlify load balancer, and the `www` CNAME that currently points at the deleted Netlify subdomain. Both get replaced with Vercel's targets:

Type	Name / Host	New Value (Vercel)	Replaces (old, Netlify)
A	@ (apex)	<code>76.76.21.21</code>	<code>75.2.60.5</code>
CNAME	<code>www</code>	<code>cname.vercel-dns.com</code>	<code>keja-ai.netlify.app</code>

1 Open the DNS editor for `keja.app`

Sign in to Spaceship and navigate to the DNS management page for the `keja.app` domain. The record list shows the current Netlify-era entries.

`spaceship.com` → Domains → `keja.app` → DNS records

2 Edit the apex A record

Find the `A` record for host `@` (the apex, sometimes displayed as the bare domain `keja.app`). Change its value from `75.2.60.5` to `76.76.21.21` — Vercel's anycast address, which routes visitors to the nearest edge region. Keep the record type as `A`; do not convert it to a `CNAME` (DNS does not allow `CNAME`s at the apex).

3 Edit the `www` `CNAME` record

Find the `CNAME` record for host `www` and change its target from `keja-ai.netlify.app` to `cname.vercel-dns.com`. If the editor shows a trailing dot (`cname.vercel-dns.com.`), that is fine — registrars treat both spellings identically. If the editor rejects the change, look for a conflicting pre-existing `A` or `AAAA` record on `www` and delete it first.

4 Save and leave everything else alone

Save both edits. Do **not** change the nameservers (`launch1/launch2.spaceship.net` stay), and do not remove other records (email `MX`, `SPF TXT`, and so on) — this migration only repoints web traffic. TTL can be left at its default; lowering it beforehand only helps if you expect to roll back quickly.

WHY ONLY THESE TWO RECORDS

The apex domain cannot be a `CNAME` (DNS does not allow it), so it points at Vercel's edge IP `76.76.21.21`. The `www` subdomain can be an alias, so it points at Vercel's `CNAME` target. Vercel also publishes a `TXT` verification record (`_vercel.keja.app`) as an alternative ownership proof — it is not needed when the `A` record points at Vercel, so you can ignore it.

Step 2 — Verify Propagation

DNS changes ripple outward from Spaceship's nameservers, usually within minutes. Verification is a pure read-only operation — run these commands from any terminal (or use an online dig tool) and compare against the expected values:

```
# 1. The apex must resolve to Vercel's anycast address
dig +short keja.app A
# expected: 76.76.21.21

# 2. www must alias to Vercel's CNAME target
dig +short www.keja.app CNAME
# expected: cname.vercel-dns.com.

# 3. The site must answer over HTTPS with Vercel headers
curl -I https://keja.app
# expected: HTTP/2 200 + an x-vercel-id response header

# 4. www must redirect to the apex (308)
curl -I https://www.keja.app
# expected: HTTP/2 308 + location: https://keja.app/
```

In the Vercel dashboard, open **keja-ai** → **Settings** → **Domains**: the status next to `keja.app` and `www.keja.app` changes from "Pending" / "Invalid Configuration" to a green **Valid Configuration** once the records resolve from Vercel's point of view. The certificate is issued at the same time — if the dashboard still shows pending but `dig` is correct, give it a few more minutes; Vercel re-checks automatically.

CERTIFICATES NEED A LITTLE TIME

In the minutes right after the switch you may see a TLS warning on `keja.app` — the DNS has moved but Let's Encrypt is still provisioning the certificate. This self-heals within about an hour and usually within minutes. Do not "fix" it by changing DNS again; just re-test after a short wait.

What Vercel Handles Automatically

Once the two records resolve, no further configuration exists anywhere — the remaining behaviour is baked into the project. It helps to know what to expect, so none of the following comes as a surprise:

- ☐ **HTTPS everywhere, always.** Let's Encrypt certificates for `keja.app` and `www.keja.app` are issued automatically and renewed behind the scenes — no expiry warnings, nothing to schedule. Plain-HTTP requests are upgraded to HTTPS at the edge.
- ☐ **www folds into the apex.** `www.keja.app` is configured as a redirect domain: it answers with a permanent 308 to `https://keja.app`, keeping a single canonical URL in search results and analytics.
- ☐ **Every deploy updates the domain.** Each green deployment is promoted to production and instantly serves from `keja.app` — no alias updates to run. `keja-ai-rho.vercel.app` keeps working as a permanent fallback URL.
- ☐ **Monitoring is already watching.** The repository's `production-check` workflow smoke-tests `keja.app` hourly once it is live — its Actions badge turns green for the domain when the switch has propagated.

SECTION 07

Post-Launch Checklist

After `curl -I https://keja.app` answers 200, run through this list once to confirm the whole surface works end to end. It takes about five minutes and covers everything the domain switch could possibly affect:

- ☐ **App loads.** Browse `https://keja.app` — search, listings, and the AI advisor all work; deep links like `https://keja.app/#/properties/KJA-001` open the right views.
- ☐ **Redirect works.** `https://www.keja.app` lands on `https://keja.app` with a padlock in the address bar.
- ☐ **PWA installs.** On Android, Chrome offers "Install app"; on iOS, Safari → Share → Add to Home Screen. The installed app launches full-screen with the Keja splash.

- ☐ **Offline shell works.** With the app installed, airplane-mode launch still shows the cached shell (the service worker version is stamped per build, so the next online visit picks up updates within a day).
- ☐ **Repo monitors go green.** GitHub → Actions → *Production check* shows both matrix entries passing (production alias + keja.app).

SECTION 08

Troubleshooting

Almost every failure mode of this setup is a propagation or stale-cache variant. Work down these tables before changing anything — most rows resolve by waiting, and unnecessary edits to DNS only extend the outage. The first table covers the DNS layer (records, certificates, Vercel's view); the second covers what users see on their devices after the DNS is already correct.

► DNS & propagation

Symptom	Likely cause	Fix
keja.app does not load yet	DNS still cached on the old values	Confirm with <code>dig +short keja.app A</code> from a different network; wait out the TTL (usually minutes)
TLS warning on keja.app	Certificate provisioning in progress	Wait up to an hour; Vercel issues the Let's Encrypt certificate automatically
www does not redirect	www CNAME still points at the old target	Re-check the record: host <code>www</code> → <code>cname.vercel-dns.com</code>
Dashboard shows "Invalid Configuration"	Vercel has not re-checked since the change	Give it a few minutes; Vercel polls automatically — or click "Refresh" on the domain row
Cannot find the DNS editor in Spaceship	Dashboard navigation differs per account state	Domains → keja.app → DNS records; if the domain was just added, wait a moment for the DNS tab to appear

► Client-side & app-level

Symptom	Likely cause	Fix
keja-ai.vercel.app shows a different app	That alias belongs to a different Vercel account (a second login)	Nothing to fix — use <code>keja-ai-rho.vercel.app</code> ; <code>keja.app</code> is the canonical domain
Works on desktop, not on phone	Mobile carrier DNS cache	Toggle airplane mode or switch networks; mobile caches are the slowest to clear
Site loads but shows old content	Browser or edge cache still holding the previous response	Hard-refresh (Ctrl/Cmd+Shift+R); service-worker installs update themselves on the next online visit
Installed PWA still opens the old URL	The home-screen shortcut kept the previous start URL	Reinstall once from <code>https://keja.app</code> — Android shows the install prompt again, iOS re-adds via Share menu

ROLLBACK PATH

If anything needs undoing, the change is fully reversible: point the A record back and the `www` CNAME back to their previous values. Vercel keeps every production deployment, so code-level rollbacks never touch DNS — dashboard → `keja-ai` → Deployments → any green build → Promote to Production.

If a problem persists beyond this table, the fastest escalation paths are, in order: the repository's engineering runbook (`docs/DEPLOYMENT.md`) which documents the exact live configuration this guide mirrors; the Vercel dashboard's deployment and domain logs, which show edge-side errors that DNS tools cannot see; and Vercel support itself, reachable from the dashboard's help menu — the Hobby plan includes it for exactly this kind of account-level question. In practice, though, every issue seen so far with this setup has been a propagation window that closed on its own.

DOMAIN SETUP · COMPLETE

Two records, one canonical home.

Point the A record and the www CNAME at Vercel, and `keja.app` becomes the single, branded, HTTPS-everywhere home of Keja AI — with certificates, redirects and deployments all handled automatically from that moment on.

Keja AI · Africa's Real Estate Intelligence & Trust Infrastructure

Production: `keja-ai-rho.vercel.app` · Canonical: <https://keja.app>
